

SIMDAX[®] GIVES YOU TIME IN ACUTE HEART FAILURE

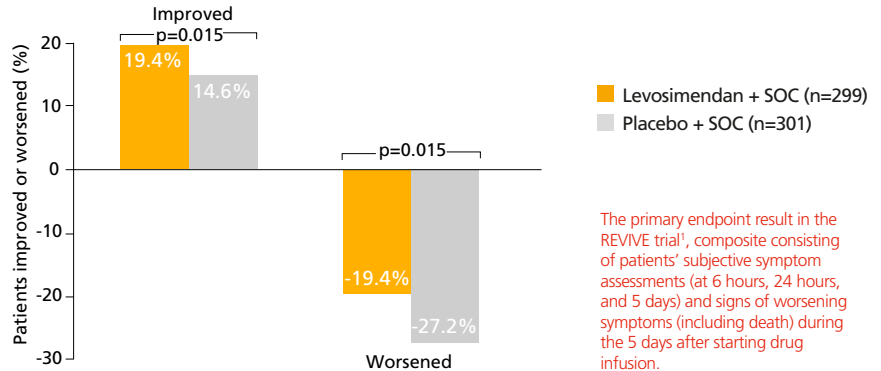

SIMDAX[®]
levosimendan

SIMDAX® RELIEVES SYMPTOMS IN AHF

SIMDAX® improves symptoms of dyspnoea and fatigue in acute heart failure. In the Phase III regulatory study REVIVE, symptoms over the 5-day assessment period improved significantly more with SIMDAX® than with placebo when administered on top of the standard of care.¹

Improvement in clinical status

The primary endpoint result in the REVIVE trial¹, composite consisting of patients' subjective symptom assessments (at 6 hours, 24 hours, and 5 days) and signs of worsening symptoms (including death) during the 5 days after starting drug infusion.

Improvement in dyspnea

Effects of levosimendan vs placebo on top of standard of care on dyspnea in patients with AHF.⁴

*Includes mild, moderate and marked improvement on a 7-point scale

Reference: 1. Packer M. et al. *JCHF*. 2013;1(2): 103-11.

...WITH SUSTAINED HEMODYNAMIC AND NEUROHORMONAL EFFECTS

The hemodynamic effects of SIMDAX® on cardiac output (CO) and pulmonary capillary wedge pressure (PCWP) have been shown in several clinical trials.¹⁻³

The effect of SIMDAX is sustained,^{1,4} as also seen in a prolonged decrease of brain natriuretic peptide in the SURVIVE clinical trial.⁴

Sustained hemodynamic effects

Figure 1: Duration of action of 24-hour infusion of levosimendan.¹ CO = Cardiac Output; PCWP = pulmonary capillary wedge pressure

Sustained effects on neurohormone levels

Figure 2: Rapid and sustained reduction in B-type natriuretic peptide. In SURVIVE, a double-blind randomized, multicenter study comparing levosimendan and dobutamine in 1327 patients hospitalized for AHF, a more profound reduction in BNP was seen with levosimendan.⁴

...THE BENEFITS ARE PRONOUNCED IN THE PRESENCE OF β -BLOCKERS

In the ESC heart failure guidelines¹ SIMDAX[®] is recommended for acute heart failure in patients with reduction of cardiac output and in presence of β -blockers.¹

SIMDAX[®] can be used in patients receiving beta-blocking agents without loss of efficacy.²

Indeed a beneficial effect on 31 days survival is also noticeable in presence of β -blockers.³

Effect of previous beta-blocker use on cardiac output (CO) and pulmonary capillary wedge pressure (PCWP) after a 24-hour infusion of levosimendan or dobutamine at 24 hours post-baseline (LIDO)²

Day	Use of β -blocker	Favours		Deaths, N (%)		P-value	
		Levosimendan	Dobutamine	Levosimendan	Dobutamine	HR	Interaction
0-5	Yes	[Forest plot point estimate]		5 (1.5)	17 (5.1)	0.01	0.03
	No	[Forest plot point estimate]		24 (7.3)	23 (7.0)	0.87	
0-14	Yes	[Forest plot point estimate]		15 (4.5)	25 (7.5)	0.10	0.16
	No	[Forest plot point estimate]		44 (13.4)	44 (13.3)	1.00	
0-31	Yes	[Forest plot point estimate]		24 (7.1)	31 (9.3)	0.29	0.55
	No	[Forest plot point estimate]		55 (16.8)	60 (18.2)	0.62	

Hazard ratio (95 % CI)

Hazard ratios for all-cause mortality rates up to 31 days after levosimendan and dobutamine therapy (SURVIVE) stratified for beta-blocker use at the start of the study.²

HOW TO USE SIMDAX® IN AHF

Example of use

AHF patients with systolic dysfunction (LVEF < 40%) and with the following characteristics may be considered for SIMDAX® treatment:

- signs of hypoperfusion, i.e. cool extremities, oliguria
- severe pulmonary oedema
- inadequate response to traditional treatment (however, the start of the SIMDAX® infusion should not be unnecessarily delayed.)

Exclusion criteria

- severe hypotension and/or tachycardia
- severe renal impairment
- severe hepatic impairment
- history of Torsades de Pointes

Dosing

Dosing of SIMDAX® will be according to the SPC. However, the bolus dose should only be given if immediate effects are needed and the baseline blood pressure is > 120 mmHg.¹ Thus, in most cases:

- SIMDAX®-infusion will be started with an infusion rate of 0.1 mcg/kg/min.
- The rate can be increased to 0.2 mcg/kg/min if further effect is warranted or decreased to 0.05 mcg/kg/min if adverse effects (e.g. hypotension) occurs.
- The maximum duration of the infusion should not exceed 24 hours.

What to expect?

Haemodynamic and neurohormonal effects

Pulmonary capillary wedge pressure ↓↓↓

Cardiac output (index) ↑↑

Stroke volume ↑

Systemic vascular resistance ↓↓

Pulmonary vascular resistance ↓↓

Natriuretic peptide levels ↓↓↓

↓ = decrease, ↑ = increase

Other clinical effects

Relief of symptoms of heart failure

Effects maintained also with beta-blockers

Sustained effects due to an active metabolite

No development of tolerance

No increase in myocardial oxygen consumption

Anti-ischemic effect

No impairment of diastolic function

Reference: 1. Nieminen MS *et al.* *Heart Lung Vessels.*

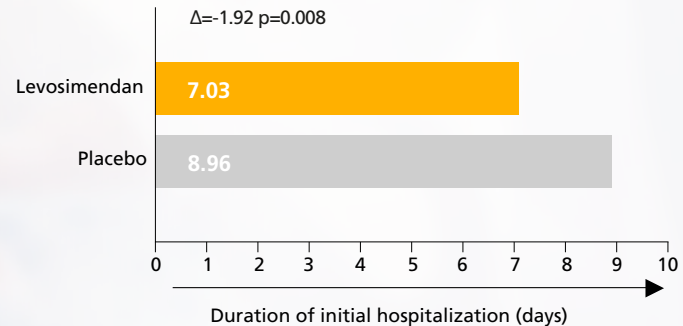

IN AHF THE EFFECTS OF SIMDAX® ALLOW A SHORTER HOSPITAL STAY

SIMDAX®, on top of standard of care, shortens hospital stay in acute heart failure. These data have been shown in a phase III study (vs placebo).^{1,2}

Hospital stay is reduced by

1.92 DAYS

Hospitalization length of acute heart failure patients

References: 1. De Lissoyoy G et al. *Eur J Health Econ.* 2010;11:185–193. 2. Packer M et al. *JACC Heart Fail.* 2013;1(2):103-11

Data from an economic analysis of the REVIVE II study of 600 patients hospitalized for treatment of acute decompensated heart failure!

...WHICH IS CONFIRMED BY META-ANALYSIS OF SEVERAL STUDIES

These results are corroborated by a meta-analysis of 8 studies in which SIMDAX® was used in cardiology settings:

Length of stay in hospital was decreased by 1.59 days in SIMDAX® treated patients in addition to a significant reduction in mortality.¹

Meta-analysis of the levosimendan effects on length of stay in hospital¹

BETTER OUTCOME THAN WITH OTHER VASOACTIVE I.V. AGENTS

ALARM-HF¹ registry

The effect of i.v. vasoactive drugs on in-hospital mortality was studied in 4,953 AHF patients (Figure 1. unadjusted analysis).

A propensity-based analysis was performed to compare in-hospital mortality of patients treated only with SIMDAX[®] versus those treated with only catecholamines showing a significant reduction in the risk of in-hospital mortality (HR 0.25, 95% CI 0.07–0.85).

Reference: 1. Mebazaa A *et al. Intensive Care Med.* 2011;37:290-301.

Figure 1: Effect of the main intravenous (IV) drugs administered during first 48 h in acute heart failure (AHF) patients on in-hospital mortality.

...WITH NO COMPROMISE ON LONG-TERM SURVIVAL

The use of SIMDAX[®] was associated with improved survival.

A meta-analysis of 23 studies describing the use of SIMDAX[®] in cardiology settings showed a 25% risk reduction [SIMDAX[®] 441/2207 (20.0%), control 484/1893 (25.6%), RR=0.75 (95% CI 0.63, 0.91), p for effect: 0.003, p for heterogeneity: 0.131, NNT=18].¹

Reference: 1. Landoni G *et al. Crit Care Med.* 2012;40:634–646.

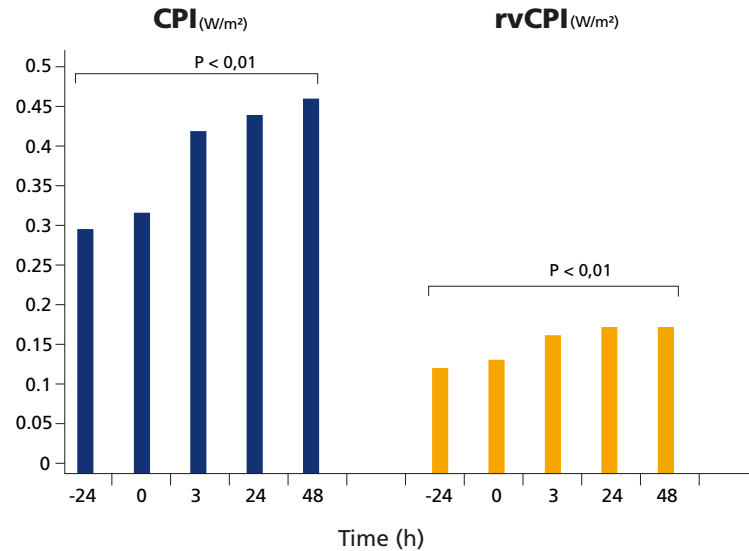

Meta-analysis on mortality of levosimendan clinical trials in cardiology settings¹

IMPROVEMENT OF HEMODYNAMIC PARAMETERS IN CARDIOGENIC SHOCK

SIMDAX® increases cardiac index in patients who did not improve with conventional therapy (including use of dobutamine and norepinephrine)¹

Levosimendan has effects on both left and right ventricular performance

Reference: 1. Russ MA et al. Crit Care Med. 2009;37:3017-23

-24 = 24 h before levosimendan application;
0 = application of levosimendan after conventional therapy;
3, 24, 48 = time after levosimendan application

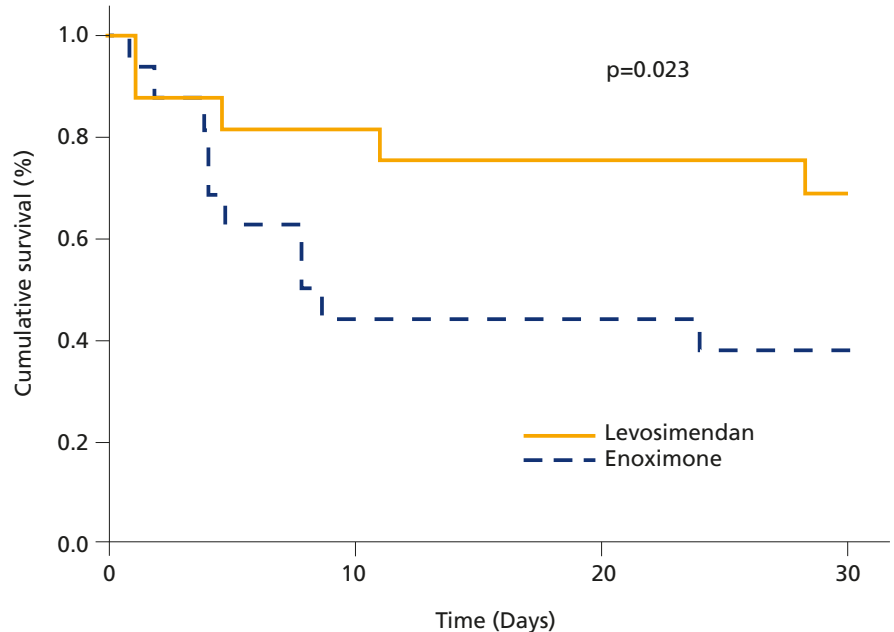

...WITH NO COMPROMISE ON OUTCOME

SIMDAX® was compared with enoximone in 32 patients with refractory cardiogenic shock complicating acute myocardial infarction.¹

The standard of care consisted of immediate revascularisation by percutaneous coronary intervention, IABP, fluid resuscitation and conventional inotropes.

SIMDAX® use was associated with similar hemodynamic effects, but mortality was significantly lower.

30 day survival in patients with cardiogenic shock

Reference: 1. Fuhrmann JT et al. *Crit Care Med.* 2008 ;36:2257-66.

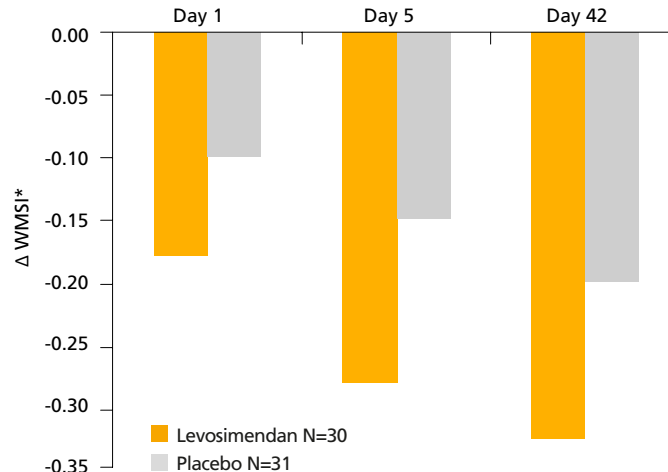

IMPROVEMENT OF LEFT VENTRICULAR FUNCTION IN HEART FAILURE AFTER ACUTE CORONARY SYNDROME

Sixty patients developing clinical signs of heart failure or cardiogenic shock within 48 hours after a primary percutaneous coronary intervention were randomized to a 25 hour infusion of SIMDAX® or placebo.¹

SIMDAX® significantly improved the change in wall motion score index from baseline to day 5 as measured by echocardiography (see chart).¹

One and four patients died in the SIMDAX® and placebo groups, respectively.¹

Levosimendan effect on wall motion score index in acute heart failure following acute coronary syndrome

Change in wall motion score index between patients treated with a 25 hour infusion of levosimendan (n=30) or placebo (n=31), mean values±SEM. *Primary endpoint p=0.031.¹

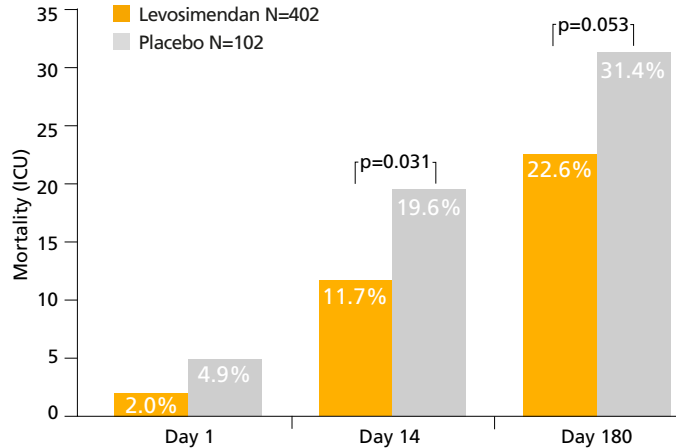

Reference: 1. Husebye T et al. *Eur J Heart Fail.* 2013;15:565–572.

...WITH NO COMPROMISE ON SURVIVAL

In the placebo-controlled RUSLAN trial, 6-hour infusions of SIMDAX® were shown to be safe in patients who developed heart failure after an acute myocardial infarction, and significantly increased survival at 14 days after administration.¹

The positive effect of SIMDAX® on survival in these settings was confirmed by a recent meta-analysis of nine studies.²

The effect of levosimendan on survival in acute heart failure following acute myocardial infarction

Mortality in 504 patients with left ventricular failure complicating acute myocardial infarction, the RUSLAN trial.¹

RECOMMENDATION ON THE USE IN ACS RELATED AHF

Expert panel consensus on the use of vasoactive drugs in acute heart failure related to acute coronary syndrome^{1,a}

Killip class	II, rales, pulmonary congestion		III, acute pulmonary edema	IV, hypotension or CS
AHF/CS, segmentation by SBP	SBP>110 mmHg	85<SBP<110 mmHg, worsening of HF	85<SBP<110 mmHg, decreasing	SBP<85 mmHg, evidence of peripheral vasoconstriction
Loop diuretic (e.g. furosemide i.v.)	+	+	+	+
β-blocker	maintain	reduce or withdraw according to patient status ^b	withdraw ^b	withdraw
Vasodilator (e.g. nitrate)	+	+ initially	+ initially	-
inotrope I.V. (e.g. dobutamine)	-	+ initially	+ in case of poor response to standard therapy	+ initially
Vasopressor i.v. (e.g. norepinephrine)	-	- not initially	- not initially	+ aiming for SBP>90 mmHg, with inotrope or inodilator
Inodilator i.v. levosimendan	-/+ (when β-blocker is used and urinary output is insufficient after diuretics)	-/+ (when β-blocker is used and urinary output is insufficient after diuretics)	+ (When SBP>90 mmHg; if hypotensive response, consider filling or combining vasopressor)	+ with vasopressor
ECMO, LVAD, (IABP ^c)	-	-	-	+ (with CI<1.8 l/min and not responding to medical treatment)

ACS = acute coronary syndrome; AHF = acute heart failure; CI = cardiac index; CS = cardiogenic shock; ECMO = extracorporeal membrane oxygenation; IABP = intra-aortic balloon pump; LVAD = left ventricular assist device; SBP = systolic blood pressure.

^a Monitoring, fluid challenge, arrhythmia care, cardiac catheter including angiography/Percutaneous Coronary Intervention (PCI). ^b Some patients in this class need β-blockade despite hemodynamic impairment, to manage ventricular arrhythmias, or to rate control AF. ^c IABP is indeed not recommended by the most recent STEMI ESC guidelines but in case of mechanical complication.

DOSING AND MONITORING IN ACS RELATED AHF

SIMDAX® dosing:¹

- The recommended infusion rates are 0.05–0.1 µg/kg/min for 24 hours
- Bolus dose should be avoided due to the risk of hypotension. If a faster onset of action is needed, an infusion of 0.2 µg/kg/min could be used during the first 60 min

Monitoring of treatment:¹

- Hypotension, a potential side effect of SIMDAX®, is of particular concern in patients with ACS
- Continuous hemodynamic monitoring is recommended. This includes ECG, blood pressure, SaO₂, heart rate, urinary output, potassium levels, and clinical signs. End-organ function (liver, kidney, mental status) should be evaluated

EASING THE CHALLENGE OF TREATING THE FAILING HEART¹ WITH LONG LASTING HEMODYNAMIC STABILIZATION

SIMDAX[®] GIVES YOU TIME BY PROVIDING:

- Hemodynamic improvement^{2,3}
- Symptomatic improvement^{2,3}
- Sustained effects²
- Synergies with β -blockers⁴
- Shorter hospital stay^{5,6}
